#### **Question No: 12**

Implement RSA algorithm using client-server concept. Using this illustrate secret key distribution scenario with confidentiality and authentication. The program should support the following:

- i. Both client and server generate {PU, PR} and distribute PU to each other.
- ii. Establish a secret key K between client and server by exchanging the messages as shown in below figure.

## [CO4,PO1 to PO4,PO9]

## Algorithm:

i. Both client and server generate {PU, PR} and distribute PU to each other.

- ii. Establish a secret key K between client and server by exchanging the messages as shown in below figure.
  - **1.** A uses B's public key to encrypt a message to B containing an identifier of  $A(ID_A)$  and a nonce  $(N_1)$ , which is used to identify this transaction uniquely.
  - 2. B sends a message to A encrypted with  $PU_a$  and containing A's nonce  $(N_1)$  as well as a new nonce generated by B  $(N_2)$ . Because only B could have decrypted message (1), the presence of  $N_1$  in message (2) assures A that the correspondent is B.
  - 3. A returns  $N_2$ , encrypted using B's public key, to assure B that its correspondent is A.
  - 4. A selects a secret key  $K_s$  and sends  $M = E(PU_b, E(PR_a, K_s))$  to B. Encryption of this message with B's public key ensures that only B can read it; encryption with A's private key ensures that only A could have sent it.
  - 5. B computes  $D(PU_a, D(PR_b, M))$  to recover the secret key.
